

Data Structures & Algorithms Lab Project

Version Control System

Submitted to: Mam. Raena Tauqir

Introduction

- **Version control systems** are software tools that help software teams manage changes to source code over time
- Version Control Management System helps manage your code efficiently
- You can track the history of project
- Our Project is a minimal clone of a very popular version control system “Git”.

Background

- Git is a popular version control system that was initially created by Linus Torvalds for development of the Linux Kernel.
- managing the code like remote work issue, code review issues & tracking bugs was impossible.
- To overcome this issue Centralized Version Control Systems (CVS) were introduced.
- CVS had an issue of making changes in central version.
- To avoid that issue Distributed Version Control (DVS) System was introduced like Git.

Features

- You can manage your code efficiently by making different versions of project
- You can work on different modules of project without being dependent on other peoples' work
- Track the history of project
- If applications stop working because of some issue it's easy to find bugs.

Features

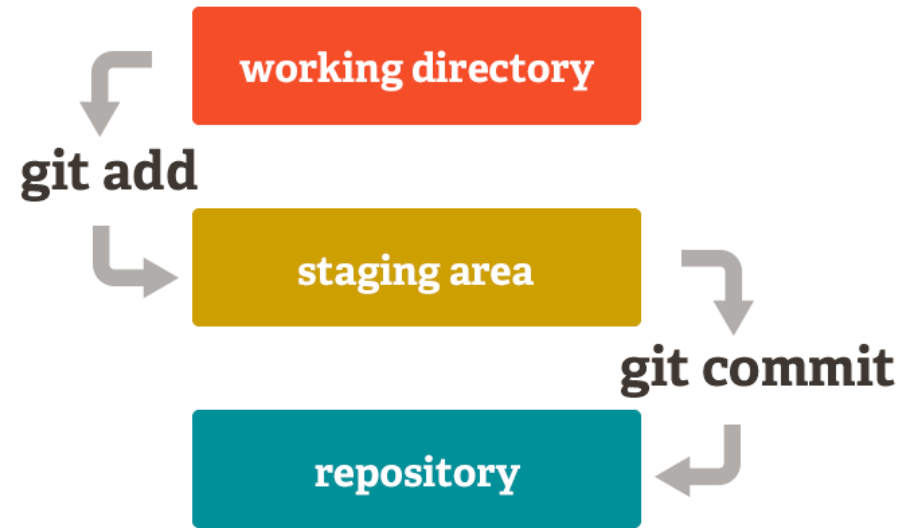

- As in our project which is a simple clone of Git Version Control System.
- You can add your code to staging area.
- Make commits to create different versions of project files.
- Display all the commits OR versions in console.
- Even Revert back to a previous version commit.
- Track changes.

but how does it work?

- Basically It's divided into 3 Main Parts
- LET'S SEE

WORKING – BASIC IDEA

you enter the Mall \longrightarrow `<git init>` initialization for .git folder

you collect items in your trolley \longrightarrow `<git add .>` adding all source files in staging area to prepare for committing

you go to cashier, bill is made & you take your items \longrightarrow `<git commit>` all changes are committed and a version OR backup is made

WORKING – PROJECT REFERENCE

- All the functions work using the command arguments passed by user when using terminal environment.
- This works by using `argc` & `*argv[]` in main function.
- `argc` & `argv` are how command line arguments are passed to `main()` in C and C++
- `argc` will be number of arguments of string type and `*argv[]` is an array that contains those arguments
- With each commit, a new directory is created
- and hence every time an instance of the program runs it iterates through linked list nodes created using directory paths.

WORKING – PROJECT REFERENCE

TERMINAL

@user: ./git init
repository initialized

./currentDirectory

index.html
style.css
script.js

DIRECTORIES CREATED

| |
|--------------------|
| ./git |
| ./git/staging_area |
| ./git/commits |

@user: ./git add .
files added to staging area

./currentDirectory

index.html
style.css
script.js

FILES COPIED TO STAGING_AREA

| |
|---|
| ./git/staging_area/ index.html style.css script.js |
|---|

@user: ./git commit -m "version 1"
files moved from staging area to commit folder

./currentDirectory

index.html
style.css
script.js

COMMIT DIR CREATED WITH RANDOM ID

| |
|--|
| ./git/commits/ index.html style.css script.js |
|--|

WORKING – HOW COMMITS WORK AS NODES

addOnTail(commit Msg)

IF(!checkHead()) → if commits folder is empty

.git/commits/

```
commitID: 0x1111  
commitInfo.txt: 1.commitID  
                 2.commitMsg  
                 3.data/time
```

~~nextCommitID~~

DATA

IF(checkHead()) → if commits folder is not

.git/commits/

```
commitID: 0x1111  
commitInfo.txt: 1.commitID  
                 2.commitMsg  
                 3.data/time
```

nextCommitID: 5x24Afd2

DATA

```
commitID: 5x24Afd2  
commitInfo.txt: 1.commitID  
                 2.commitMsg  
                 3.data/time
```

~~nextCommitID~~

DATA

Code Structure – main.cpp

```
18 int main(int argc, char *argv[])
19 {
20     gitClass gitClassObj;
21     if(argc >= 2)
22     {
23         string argument = string(argv[1]);
24         //git init
25 >     if (argument == "init") ...
31         //git add
32 >     else if (argument == "add") ...
62         //git commit
63 >     else if (argument == "commit") ...
82         // git revert
83 >     else if(argument == "revert") ...
105         // //git log
106 >     else if(argument == "log") ...
110         //git status
111 >     else if(argument == "status") ...
115         //wrong arguments
116 >     else ...
120
121     }
122     else
```

Code Structure – gitClass.cpp

```
20  class gitClass
21  {
22  public:
23      commitNodeList list;
24      void gitInit();
25      void gitAdd();
26      void gitAdd(string files[], int arrSize);
27      void gitCommit(string msg);
28      void gitRevert(string commitHash);
29      void gitLog();
30      void gitStatus();
31  };
32
33 > void gitClass::gitInit() ...
39
40 > void gitClass::gitAdd() ...
60
61 > void gitClass::gitAdd(string files[], int arrSize) ...
94
95 > void gitClass::gitCommit(string msg) ...
99
100 > void gitClass::gitRevert(string commitHash) ...
104
105 > void gitClass::gitLog() ...
109
110 > void gitClass::gitStatus() ...
114
```

Code Structure – commitNodeList.cpp

```
42 class commitNode
43 {
44 private:
45     string commitID;
46     string commitMsg;
47     string nextCommitID;
48     commitNode *next;
49
```

```
179 class commitNodeList
180 {
181 private:
182     commitNode *HEAD;
183     commitNode *TAIL;
184
185     bool checkHead()
186     {
187         // check if HEAD commit exists
188         auto tempDir = filesystem::current_path() / ".git" / "commits" / "0x1111";
189         return filesystem::exists(tempDir);
190     }
191
192 public:
193     commitNodeList()
```

Takeaway

- This is a simple clone of the same git version control system
- It shows you how you can work with files and filesystem in your operating system
- shows you how you can make use of version control management system to better track your project files.
